# You've got a wedgie!

A pocket computer: a Raspberry Pi Pico, a screen, and a secure chip wedged in between. It runs one app at a time: games, tools, or a wallet signer.

1. **Go to wedgie.dev in Chrome.**
2. **Plug in your wedgie.**
3. **Click the green button on wedgie.dev.**
4. **Update the firmware.**
5. **Install an app...**

Screen doesn't light up? Turn the cable around: swap which end goes in the wedgie. Some only work one way.

## Get started

1. Plug it into a computer with a **USB data cable**: **USB-C** or **micro USB**, depending on the Pico inside (some cables only charge). The screen lights up. **No light? Turn the cable around**: swap which end goes in the wedgie. Some only work one way.
2. A drive called **WEDGIE** shows up. Open **Open wedgie** on it, or go to **wedgie.dev/connect** in **Chrome** or **Edge**. Safari and Firefox can't talk to USB.
3. Click the green **Allow wedgie connection** button, top right. Pick your wedgie.
4. **Update the firmware** if it asks. Always. Press **green** on the wedgie.
5. Pick an app. The wedgie asks **Install?** on its screen. Press **green**.

## Apps

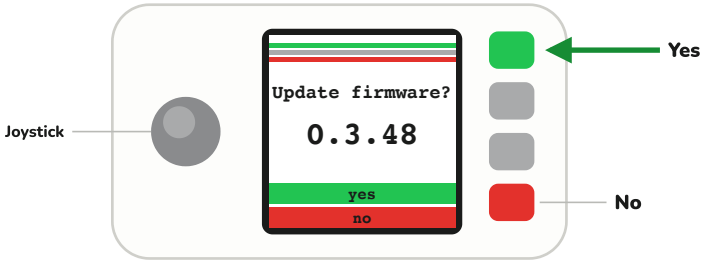

Games: Frog, Grove, Bunker, Blocks, 2048, Blackjack. Tools: Buttons, Keypad. And **Safe Signer**, a hardware signer for a Safe multisig. More every week.

Switch apps anytime at **wedgie.dev/connect**. Game saves stay when you switch or update.

## Make your own app

Go to **wedgie.dev/code**. Write it yourself, or have your AI agent write it. Try it in the browser, then put it on your wedgie. Agents: read **wedgie.dev/skill.md**.

## The buttons

**Green says yes. Red says no.** When the wedgie asks, like here, press green to update. The joystick and gray buttons do whatever the app wants.

## Is it safe?

- **Plugging it in gives a computer nothing.** It's locked.
- **Nothing installs or signs without a press of green** on the wedgie itself. No website or program can press it.
- **Apps on the shelf and the firmware are signed** by wedgie.dev. The wedgie checks before it installs.
- **Keys are made inside the secure chip** and never leave it.

An app can do anything on the wedgie. Only install apps from the shelf, or code you trust.

## Safe Signer

Makes your wedgie an owner of a Safe multisig. Install it, then go to **wedgie.dev/safe**.

- The first time it opens, it says **No key**. Press green: the chip makes a key and **locks it for good**. Nobody ever sees it, not even us.
- It shows what a transaction does. Green signs, red says no.
- Keep a second owner on your Safe. If the chip breaks, its key is gone.

**Make your own key.** The first time you open Safe Signer it must say **No key**. If it already shows an address, someone made a key before you. Don't use it. Email us.

## If something's off

**The screen doesn't light up**
Turn the cable around: swap which end goes in the wedgie. Some only work one way. Still dark? Try another cable.

**It doesn't show up on the computer**
Try another cable (charge-only cables are common) and another USB port.

**An app is stuck or crashes when it starts**
Hold **both gray buttons** while you plug it in. It starts without the app. Then pick another app.

**"wedgie broke"**
Press the **gray button next to green** to try again.

**The page says the firmware is old**
Click update and press green on the wedgie.

**Still broken**
Go to **wedgie.dev/test** in Chrome. It wipes the wedgie, puts everything back on, and tests the screen, buttons and chip. Your game saves come back. It never touches the chip's keys. To wipe it, push a paperclip into the small hole in the base while you plug it in.

## Help

Email **wedgie@buidlguidl.com**
Show it off: **@wedgiedev** on X.
